1 Normal Mixture Revisited

Consider a normal mixture, prior for $\mu_1, \mu_2 \sim N(0, 10^2)$, and the prior for $1/\sigma_1^2, 1/\sigma_2^2 \sim \Gamma(0.5, 10)$. Further, all the priors are independent.

First, the mixture normal distribution is

$$f(x) = \delta N(\mu_1, \sigma_1^2) + (1 - \delta)N(\mu_2, \sigma_2^2)$$

Since $\frac{1}{\sigma_1^2}$, $\frac{1}{\sigma_2^2} \sim \Gamma(0.5, 10)$, σ_1^2 , $\sigma_2^2 \sim \text{Inv-Gamma}(0.5, 10)$. So the posterior density is

$$\pi(\theta|\mathbf{x}) \propto \prod_{i=1}^{n} f(x_i) \times \frac{1}{\Gamma(0.5)10^{0.5}} \left(\frac{1}{\sigma_1^2}\right)^{1.5} e^{-\frac{1}{10\sigma_1^2}} \times \frac{1}{\Gamma(0.5)10^{0.5}} \left(\frac{1}{\sigma_2^2}\right)^{1.5} e^{-\frac{1}{10\sigma_2^2}} \times \frac{1}{10\sqrt{2\pi}} e^{-\frac{\mu_1^2}{2\times 10^2}} \times \frac{1}{10\sqrt{2\pi}} e^{-\frac{\mu_2^2}{2\times 10^2}}$$

where $\theta = (\delta, \mu_1, \mu_2, \sigma_1^2, \sigma_2^2)$.

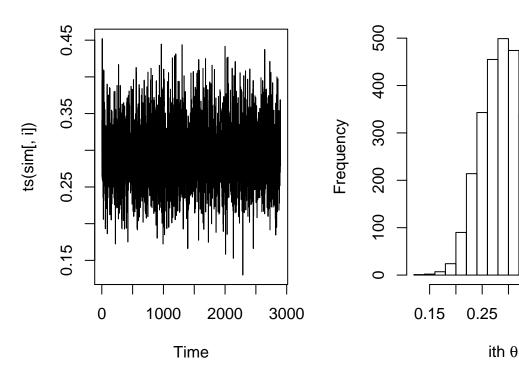

```
library('invgamma')
library('HI')
delta <- 0.7
n <- 100
set.seed(123)
u <- rbinom(n, prob = delta, size = 1)
x \leftarrow rnorm(n, ifelse(u == 1, 7, 10), 0.5)
logll <- function(theta, x){</pre>
  delta <- theta[1]
  mu1 <- theta[2]</pre>
  mu2 <- theta[3]</pre>
  sg1 \leftarrow theta[4]
  sg2 <- theta[5]
  sum(log(delta*dnorm(x, mu1, sg1^0.5)+(1-delta)*dnorm(x, mu2, sg2^0.5)))
}
loglr <- function(theta){</pre>
  delta <- theta[1]</pre>
  mu1 <- theta[2]
```

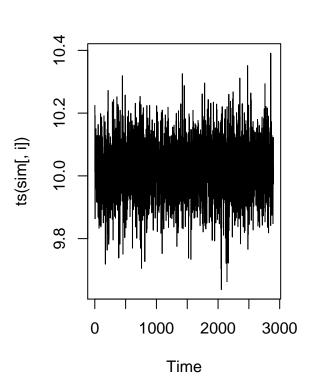

^{*}qinxiao.shi@uconn.edu

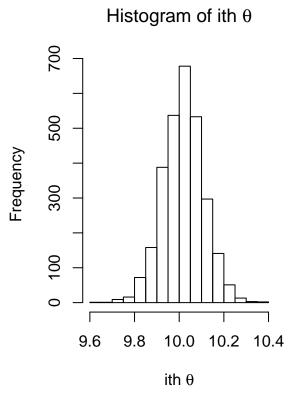

```
mu2 <- theta[3]
  sg1 <- theta[4]
  sg2 <- theta[5]
  return(dnorm(mu1, 0, 10, \log = T)+dnorm(mu2, 0, 10, \log = T)+
        dinvgamma(sg1, shape = 0.5, scale = 10, log = T)+dinvgamma(sg2, shape = 0.5, scale = 10
  )
  }
logpost <- function(theta, x) {</pre>
  delta <- theta[1]</pre>
  mu1 <- theta[2]</pre>
  mu2 <- theta[3]</pre>
  sg1 <- theta[4]
  sg2 <- theta[5]
  return(logll(theta, x)+loglr(theta))
}
mymcmc <- function(niter, thetaInit, x, nburn= 100) {</pre>
  p <- length(thetaInit)</pre>
  thetaCurrent <- thetaInit</pre>
  logFC <- function(th, idx) {</pre>
    theta <- thetaCurrent
    theta[idx] <- th
    logpost(theta, x)
  out <- matrix(thetaInit, niter, p, byrow = TRUE)</pre>
  ## Gibbs sampling
  for (i in 2:niter) {
    for (j in 1:p) {
    if (j == 1 | j == 4 | j == 5){
      out[i, j] <- thetaCurrent[j] <-</pre>
        HI::arms(thetaCurrent[j], logFC,
                  function(x, idx) ((x > 0) * (x < 1)),
                  1, idx = j)
    } else if (j == 2 | j == 3) {
      out[i, j] <- thetaCurrent[j] <-</pre>
        HI::arms(thetaCurrent[j], logFC,
                  function(x, idx) ((x > -50) * (x < 50)),
                  1, idx = j
    }
    }
  }
  out[-(1:nburn), ]
```

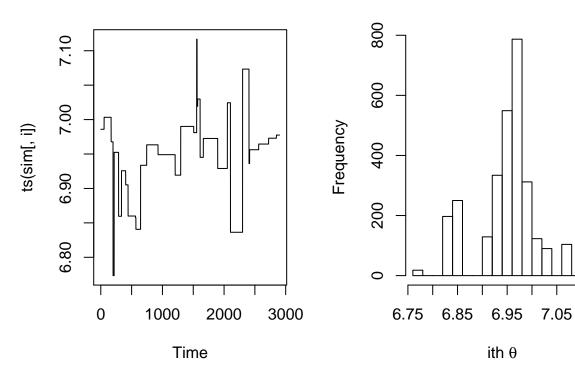

0.35

0.45

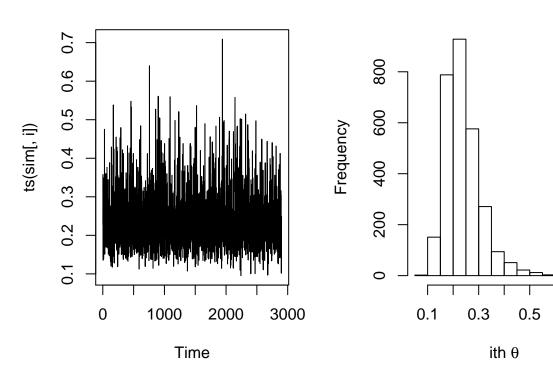

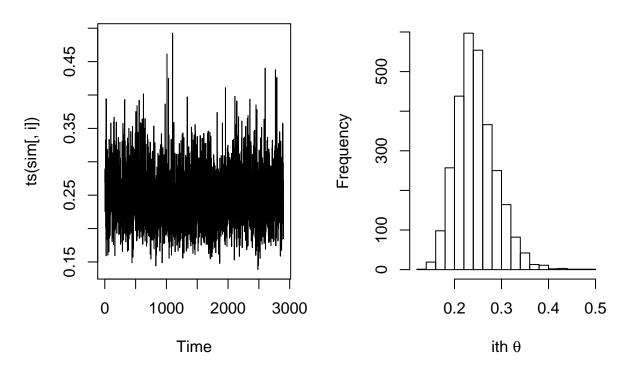

0.7

So the estimated values of θ are

$$\delta = 0.3, \mu_1 = 10, \mu_2 = 7, \sigma_1^2 = 0.25, \sigma_2^2 = 0.24$$

.
